

Statistics 360: Advanced R for Data Science

Lecture 2

Becky Lin

R Data Structures

Vectors

Subsetting

Matrices, data frames and tibbles

Logical and relational operators

Reading

- ▶ Text, chapters 3 and 4

R Data Structures

R Data Structures

- ▶ Some people think that there are four common object types store data in R:
 - ▶ Scalars: store a single numeric value.
 - ▶ String: store a set of one or more characters.
 - ▶ Vector: store several scalar or string elements.
 - ▶ Data Frames: store several vectors (meaning that they contain several rows and columns)
- ▶ Fundamentally, all common data structures in R are **vectors**, which can be “**atomic**” or “**list**”.
- ▶ R has no true **scalars** (a special syntax to create an individual value), everything that looks like a scalar is actually a vector of one. e.g., in `x<-1`, `x` is a vector of length one.
- ▶ Use `str()` to see the structure of an object

Types of objects

- ▶ All R objects have a “type”, that describes how it is stored in computer memory.
- ▶ Common types we will encounter are “logical”, “integer”, “double”, “character” and “list”.
 - ▶ Find the type of an object with `typeof()`.

```
x <- 6 # stores as double by default
typeof(x)
```

```
## [1] "double"
```

```
y <- 6L # The "L" suffix forces storage as integer
typeof(y)
```

```
## [1] "integer"
```

```
class(y)
```

```
## [1] "integer"
```

Type, class and mode

In addition to the type of an object, there is its “mode” and “class”.

- ▶ `typeof()` gives the type of objects from R's point of view.
- ▶ `class()` is used to define/identify what “type” an object is from the point of view of object-oriented programming in R. e.g., `class(y)` gives “integer”, this means any generic function that has an “integer” method will be used.
- ▶ `mode()` gives the type of object from the point of view of Becker, Chambers and Wilks (1988).
 - ▶ More compatible with other S implementation.
 - ▶ The mode of an object is generally the same as its type, but the modes are coarser. For example, integer and double types are both of mode “numeric”.

```
c(mode(x) ,mode(y) )
```

```
## [1] "numeric" "numeric"
```

Reference: [Stack overflow discussion thread](#)

Vectors

Vectors

- ▶ Two types of vector: can be either atomic or list
 - ▶ **Atomic**: all elements must be the same type.
 - ▶ **List** (“generic vectors”): objects can be of different types.
 - ▶ (low-key third type) **NULL**: absence of vector.

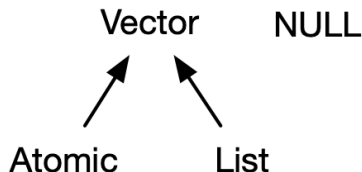

Figure 1: vector types

The null object

- ▶ The null object, NULL, is an un-typed no-value object.
 - ▶ Test for NULL with `is.null()`
 - ▶ NULL can be used to initialize objects that will be created through combining, rbinding, etc.

```
x <- NULL; is.null(x)
```

```
## [1] TRUE
```

```
x <- c(x,1); x <- c(x,2); x
```

```
## [1] 1 2
```

```
# etc., or as a loop (more on these later)
```

```
x <- NULL
for(i in 1:2) {
  x <- c(x,i)
}
x
```

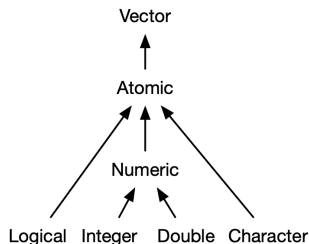

```
## [1] 1 2
```

Types of atomic vector

Four primary types of atomic vectors:

1. Logical: either be written in full (TRUE or FALSE), or abbreviated (T,F)
2. Integer: exactly an integer. Assign them by adding L behind it (for “long integer”). e.g., -1L, 0L, 1L, 2L, etc.
3. Double: decimal numbers. e.g., 1, 1.0, 1.02 ... Note that Inf, -Inf, NaN are also doubles.
4. Character: anything in quotes.

Integers and doubles are together called “numeric”

Creating empty vectors and combining vectors

- ▶ Use `vector()` to create an empty vector

```
avec <- vector(mode="double",length=4) # shorthand: avec <- double()
lvec <- vector(mode="list",length=3)   # shorthand: lvec <- list()
```

- ▶ Use `c()` to combine vectors

```
avec <- c(54,210,77)
lvec <- list(54,210,c("grey","thin"))
c(avec,c(100,101))
```

```
## [1] 54 210 77 100 101
```

```
c(lvec,TRUE)
```

```
## [[1]]
```

```
## [1] 54
```

```
##
```

```
## [[2]]
```

```
## [1] 210
```

```
##
```

```
## [[3]]
```

```
## [1] "grey" "thin"
```

```
##
```

```
## [[4]]
```

```
## [1] TRUE
```

Lists and combining lists

- ▶ Lists are like vectors except each element of it can be of any type.
- ▶ `c()` concatenates two lists, which may or may not be what you intend.

```
ll1 <- list(a=1:2,b=3:4); ll2 <- list(a=5:6,b=7:8)  
c(ll1,ll2) # not the same as list(ll1,ll2)
```

```
## $a  
## [1] 1 2  
##  
## $b  
## [1] 3 4  
##  
## $a  
## [1] 5 6  
##  
## $b  
## [1] 7 8
```

- ▶ if you use `c()` with a list and a vector, then it will first coerce the vector into a list where each element is a list.

```
ll1 <- list(a=1:2,b=3:4);  
c(ll1,c("c","d"))  # same as: c( ll1, as.list(c("c","d"))) )
```

```
## $a  
## [1] 1 2  
##  
## $b  
## [1] 3 4  
##  
## [[3]]  
## [1] "c"  
##  
## [[4]]  
## [1] "d"
```

- ▶ Use `unlist()` to remove the list structure.

```
unlist(ll1)
```

```
## a1 a2 b1 b2  
## 1 2 3 4
```

► A list of lists:

```
c(list(l11),list(l12)) # keep this in mind for the project
```

```
## [[1]]  
## [[1]]$a  
## [1] 1 2  
##  
## [[1]]$b  
## [1] 3 4  
##  
##  
## [[2]]  
## [[2]]$a  
## [1] 5 6  
##  
## [[2]]$b  
## [1] 7 8
```

Determine type and length of a vector

- ▶ You can determine the type of a vector with `typeof()`
- ▶ The special values (infinite and undefined values): `Inf`, `-Inf`, and `NaN` are doubles. Test for `Inf` and `NaN` with `is.infinite()` and `is.nan()`.
- ▶ You can check the specific type with `is.logical()`, `is.integer()`, `is.double()`, and `is.character()`.
- ▶ Missing values are represented by `NA` which is technically a logical value.
 - ▶ This rarely matters because logicals get coerced to other types when needed.
 - ▶ Never use `==` when testing for missingness. It will return `NA` since it is always unknown if two unknowns are equal.
 - ▶ Test for and set missing values with `is.na()`.
- ▶ Attempting to combine vectors of different types coerces them to the same type. The order of preference is `character` > `double` > `integer` > `logical`.

```
typeof(list(a=2,b=3))
```

```
## [1] "list"
```

```
x <- 1:3; typeof(x)
```

```
## [1] "integer"
```

```
length(x)
```

```
## [1] 3
```

```
is.integer(x)
```

```
## [1] TRUE
```

```
typeof(NA)
```

```
## [1] "logical"
```

```
typeof(c(1L, NA)) # logicals get coerced to other types
```

```
## [1] "integer"
```

```
typeof(c(Inf,-Inf, NaN))
```

```
## [1] "double"
```

```
typeof(c(2L,TRUE, 98.0)) # different types coerces to the same type
```

```
## [1] "double"
```

Test your knowledge

Predict R output for the following R code

```
x <- c(1,2,3, NA)
typeof(x)
is.na(c(1,2,3, NA))
is.na(x) <- 2 # set 2nd element of x to be NA
x
is.finite(c(1,Inf,-Inf, NaN))
is.infinite(c(1,Inf,-Inf, NaN))
is.nan(c(1,Inf,-Inf, NaN))
typeof(c("hello",9L, TRUE))
# exercise from Advanced R
c(1, FALSE)
c("a", 1)
c(TRUE, 1L)
1 == "1" # TRUE
-1 < FALSE # TRUE
"one" < 2 # FALSE
```

Vector attributes

- ▶ Attributes are meta information applied to atomic vectors.
- ▶ Many common objects (like matrices, arrays, factors, date-times) are just atomic vectors with special attributes.
- ▶ Vectors have type,length and, optionally, attributes such as names.
- ▶ You get and set attributes with `attr()`.
- ▶ You could see all attributes of a vector with `attributes()`.
- ▶ Attributes are name-value pairs, and all of the attributes are associated with an object. Below, the vector `c(1,2,3)` points to two attributes `x` and `y` that each have their own values.

```
a <- 1:3
attr(a,"x") <- "abecdf"
attr(a, "y") <- 4:6
attributes(a) # display all attributes
```

```
## $x
## [1] "abecdf"
##
## $y
## [1] 4 5 6
```

```
# attr(a, "x") # retrieve the x attributes of vector a
```

► Set many attributes at the same time with `structure()`

```
b <- structure(1:3, x = "abcdef", y=4:6)
attributes(b)
```

```
## $x
## [1] "abcdef"
##
## $y
## [1] 4 5 6
```

```
b # after operation
```

```
## [1] 1 2 3
## attr("x")
## [1] "abcdef"
## attr("y")
## [1] 4 5 6
```

► Most attributes are typically lost by most operations except **names** and **dim**

```
attributes(b[[1]])
```

```
## NULL
```

```
attributes(sum(b))
```

```
## NULL
```

Vector attribute - names

- ▶ Names: a character vector giving each element of the vector a name. Each name corresponds to a single element.
- ▶ You could set names using `attr()`, but you should not.

```
#This method is not recommended  
x <- 1:3  
attr(x, "names") <- c("a", "b", "c")  
x
```

```
## a b c  
## 1 2 3
```

```
attributes(x)
```

```
## $names  
## [1] "a" "b" "c"
```

```
names(x)
```

```
## [1] "a" "b" "c"
```

- ▶ Names are so special, that you could specify element names when creating a vector.

```
x <- c(a=1, b=2, c=3)
x
```

```
## a b c
## 1 2 3
```

```
attributes(x)
```

```
## $names
## [1] "a" "b" "c"
```

```
names(x)
```

```
## [1] "a" "b" "c"
```

```
# alternatively
```

```
x <- 1:3
names(x) <- c("a", "b", "c")
x
```

```
## a b c
## 1 2 3
```

```
x+2:4 # names attribute is preserved
```

```
## a b c
## 3 5 7
```

- ▶ Names stay with single bracket subsetting (not double bracket subsetting).

```
names(x[1])
```

```
## [1] "a"
```

```
names(x[1:2])
```

```
## [1] "a" "b"
```

```
names(x[[1]])
```

```
## NULL
```

- ▶ Names can be used for subsetting (more in chapter 4)

```
x[["a"]]
```

```
## [1] 1
```

- ▶ we can remove names with `unname()`

```
unname(x)
```

```
## [1] 1 2 3
```

- Attributes tend to be dropped after operation. If not, they may not make sense.

```
x <- structure(1:3,at1="abc")  
y <- structure(3:1,at1="def")  
x
```

```
## [1] 1 2 3  
## attr(,"at1")  
## [1] "abc"
```

```
y
```

```
## [1] 3 2 1  
## attr(,"at1")  
## [1] "def"
```

```
x[1:2]
```

```
## [1] 1 2
```

```
x*y
```

```
## [1] 3 4 3  
## attr(,"at1")  
## [1] "abc"
```

Vector attribute - dimension

- ▶ the `dim` attribute makes a vector into a **matrix** (a rectangle of numbers) or an **array** (a block of numbers).
- ▶ again, you could use `attr()` to set `dim()`, but you should not.

```
x <- 1:6
attr(x,'dim') <- c(2,3)
x
```

```
##      [,1] [,2] [,3]
## [1,]    1    3    5
## [2,]    2    4    6
```

```
y <- 1:12
attr(y,'dim') <- c(2,2,3)
y
```

```
## , , 1
##
##      [,1] [,2]
## [1,]    1    3
## [2,]    2    4
##
## , , 2
##
##      [,1] [,2]
## [1,]    5    7
```

- ▶ you should either use `matrix()` or `array()` to create these objects, or set the dimension with `dim()`

```
x <- 1:6
dim(x) <- c(2,3)
x
```

```
##      [,1] [,2] [,3]
## [1,]    1    3    5
## [2,]    2    4    6
dim(x)
```

```
## [1] 2 3
```

```
x <- matrix(1:6,nrow=2,ncol=3, byrow=FALSE) # byrow=FALSE,
y <- 1:12
attr(y,'dim') <- c(2,2,3)
y
```

```
## , , 1
##
##      [,1] [,2]
## [1,]    1    3
## [2,]    2    4
##
## , , 2
##
##      [,1] [,2]
## [1,]    5    7
```

- ▶ Many of the functions for working with vectors have generalisations for matrices and arrays:

Vector	Matrix	Array
<code>names()</code>	<code>rownames()</code> , <code>colnames()</code>	<code>dimnames()</code>
<code>length()</code>	<code>nrow()</code> , <code>ncol()</code>	<code>dim()</code>
<code>c()</code>	<code>rbind()</code> , <code>cbind()</code>	<code>abind::abind()</code>
<code>—</code>	<code>t()</code>	<code>aperm()</code>
<code>is.null(dim(x))</code>	<code>is.matrix()</code>	<code>is.array()</code>

Figure 3: Functions for matrices and arrays

- ▶ Instead of having names, arrays and matrices of dimnames.
The dimnames of a matrix or an array is a list the same length as the number of dimensions of the array.

```
x <- matrix(1:12,nrow=3,ncol=4)
dimnames(x) = list( c("r1","r2","r3"), c("c1","c2","c3","c4"))
x <- array(1:12, dim = c(2, 2, 3))
dimnames(x) <- list(first = c("a", "b"),
                    second = c("c", "d"),
                    third = c("e", "f", "g"))
dimnames(x)
```

```
## $first
## [1] "a" "b"
##
## $second
## [1] "c" "d"
##
## $third
## [1] "e" "f" "g"
```

```
x
```

```
## , , third = e
##
##      second
## first c d
##      a 1 3
##      b 2 4
```

- ▶ This is useful for subsetting, and for bookkeeping when you have data structured in a complicated multidimensional array (e.g. it is hard to remember what indexes the first vs second vs third dimensions without dimnames).
- ▶ A vector is not a matrix with 1 dimension, it has NULL dimensions.

```
x["a","c","g"] # easy subsetting
```

```
## [1] 9
```

```
z <- 1:3
```

```
dim(z) # nrow() and ncol() return the same result
```

```
## NULL
```

```
# Exercise: how do you get rid of the dimensions in following array?
```

```
x <- array(1:12, dim=c(2,2,3)) # two methods
```

- ▶ `nrow()` and `ncol()` return the number of rows or columns of a matrix or an array. `NROW()` and `NCOL()` do the same but they treat a vector as a 1-column matrix, even a 0-length vector.

```
z <- 1:3
```

```
nrow(z)
```

```
## NULL
```

```
ncol(z)
```

```
## NULL
```

```
NROW(z)
```

```
## [1] 3
```

```
NCOL(z)
```

```
## [1] 1
```

Exercise: predict the output

```
z0 <- NULL
```

```
NROW(z0)
```

```
NCOL(z0)
```

Vector attribute - class

- ▶ A special attribute named `class` is a key component of the “S3” object-oriented programming system (more on this later).
- ▶ Get and set with the `class()` function.
- ▶ You can set the class to `NULL` by `unclass()`.

```
lvec <- structure(list(age=54, hair="grey"), at1="abc", at2=1:3)
class(lvec) <- "prof"
lvec
```

```
## $age
## [1] 54
##
## $hair
## [1] "grey"
##
## attr("at1")
## [1] "abc"
## attr("at2")
## [1] 1 2 3
## attr("class")
## [1] "prof"
names(lvec)
```

```
## [1] "age" "hair"
```

S3 atomic vectors

- ▶ The *class* of an object is an important attribute that control R's S3 system for object oriented programming.
- ▶ The class of an object will determine its behavior when you use that class in **generic** function such as `print()`, `summary()`.
 - ▶ A generic function is a function that has different behavior based on the class of the input.
- ▶ You could create your own S3 classes (chapter 13). Here, we will talk about some S3 classes that come with R by default.

- There are four important classes of atomic vector: factors, Dates, POSIXct and difftime. We will discuss factors. See the text, section 3.4 for information on the others.

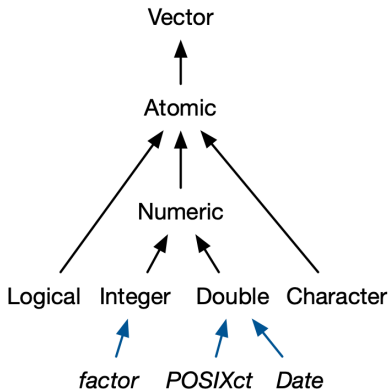

Figure 4: Vectors types in a tree

Factors

- ▶ The statistical concept of a factor is important in experimental design.
- ▶ Factors are implemented in R as atomic vectors with attributes `class` and `levels`:

```
trt <- factor(c("drug1","placebo","placebo","drug2"))  
attributes(trt)
```

```
## $levels  
## [1] "drug1"   "drug2"   "placebo"  
##  
## $class  
## [1] "factor"
```

```
str(trt)
```

```
## Factor w/ 3 levels "drug1","drug2",...: 1 3 3 2
```

- ▶ The levels are coded numerically (1, 2 and 3) with assigned labels ordered alphabetically (“drug1”, “drug2” and “placebo”) by default.
- ▶ You can specify an order to the factors with the `level` argument:

```
trt <- factor(c("drug1", "placebo", "placebo", "drug2"),  
              levels=c("placebo", "drug1", "drug2"))  
trt
```

```
## [1] drug1  placebo placebo drug2  
## Levels: placebo drug1 drug2
```

Coercion: atomic vectors to lists

- ▶ Atomic vectors can be coerced to lists with `as.list()`:

```
avec = c(age=54,weight=210,height=77)
avec
```

```
##      age weight height
##      54     210      77
```

```
as.list(avec)
```

```
## $age
## [1] 54
##
## $weight
## [1] 210
##
## $height
## [1] 77
```

Coercion: lists to atomic vectors

- ▶ Lists can be “flattened” into atomic vectors with `unlist()`:

```
unlist(lvec)
```

```
##      age      hair  
##    "54"    "grey"
```

- ▶ Notice how the numeric values are coerced to the more flexible character type.
- ▶ The order of flexibility, from least to most, is logical, integer, numeric, character.

Coercion: factors to atomic vectors

- ▶ We saw how to use `factor()` to coerce an atomic vector to a factor.
- ▶ Use `as.vector()` to coerce a factor back to an atomic vector.
- ▶ The result is a character vector. You may need to use `as.numeric()` to coerce to numeric, if required.

```
a <- factor(c(2,1,1,2))  
as.vector(a)
```

```
## [1] "2" "1" "1" "2"
```

```
as.numeric(as.vector(a))
```

```
## [1] 2 1 1 2
```

Subsetting

Subsetting and subsetting atomic vectors

Subsetting is taking out elements from an object.

- ▶ Subset because you only want some elements of a vector.
- ▶ Subset so you can assign new elements to that subset.

Six ways to subset atomic vector

1. Integer subsetting: put integers in brackets and it will extract those elements. R starts counting at 1.e.g., `x[1]`, `x[c(1,3)]`, `x[order(x)]`, `x[c(2,2,2)]`
2. Negative integer subsetting: putting negative integers will return all elements except the negative elements.e.g., `x[-1]`, `x[-c(1,3)]` same as `x[c(-1,-3)]`
3. Logical vector subsetting: wherever there is a TRUE will return the element.
`x[c(TRUE,FALSE)]`
3. No subsetting: `x[]` will return the original object.
4. zero subsetting: `x[0]` will return a zero-length vector.
5. Name subsetting: subset using those names in quotes.

List subsetting

1. if you subset a list using single brackets, `[]`, you will get a sublist. You can use integers, negative integers, logicals and names as before.
2. Using double brackets extracts a single element.
3. A shorthand for using names inside double brackets is to use dollar signs.

```
x <-list(a=1,b=2,c=3)
x[1:2]
```

```
## $a
## [1] 1
##
## $b
## [1] 2
```

```
x[["a"]]
```

```
## [1] 1
```

```
x$a
```

```
## [1] 1
```

Subsetting matrix and array

1. Include row and column indices, separated by a comma. Say M is a 3 by 3 matrix, $M[1,2]$ takes out element at $[1,2]$.
2. Have an empty space to get the whole row or the whole column. $M[1,]$ takes out first row, $M[,1]$ (same as $M[1]$) takes out first column.
3. if you want to say a matrix (not convert to a vector), use `drop=FALSE`. e.g., $M[1, , \text{drop}=\text{FALSE}]$, $M[, 1, \text{drop}=\text{FALSE}]$.
4. You could subset a matrix using just a single vector of indices, it will go in column-major order. e.g. $M[c(2,3)]$ returns values 2,3.

Subsetting arrays: similar to subsetting matrices, just add more commas.

Data Frame subsetting

1. Data frame subsetting behaviors both like lists and like matrices.
2. It behaves like a list for \$, [, and [if only provide **one index**. The columns are the elements of the list.
3. It behaves like a matrix if you provide two indices.
4. You can keep the data frame structure by using drop=FALSE
5. It is common to using filter by rows by using the matrix indexing.

```
df <- data.frame(a = 1:3, b = c("a", "b", "c"), c = 4:6)
df[1:2,2] # behaves like a matrix
```

```
## [1] "a" "b"
```

```
df[1:2,2, drop=F]
```

```
##      b
```

```
## 1 a
```

```
## 2 b
```

```
df[df$a<3,]
```

```
##      a b c
```

```
## 1 1 a 4
```

```
## 2 2 b 5
```

Subsetting with [

► Subset with [:

```
lvec <- list(age=54,weight=210,height=77,hair=c("grey","thin"))
attributes(lvec)
```

```
## $names
## [1] "age"      "weight" "height" "hair"
```

```
attr(lvec,"at1") <- "abc";attr(lvec,"at2") <- 1:3
attributes(lvec)
```

```
## $names
## [1] "age"      "weight" "height" "hair"
```

```
##
## $at1
## [1] "abc"
##
```

```
## $at2
## [1] 1 2 3
```

```
lvec[c(1,3)] # same as lvec[c("age","height")]
```

```
## $age
## [1] 54
##
## $height
## [1] 77
```

Take care using `[[` for lists

- ▶ Extract individual elements with `[[`, or `$` for named objects:

```
lvec[[4]]
```

```
## [1] "grey" "thin"
```

```
lvec$hair
```

```
## [1] "grey" "thin"
```

- ▶ `[[]]` (and `$`) can only return one item at a time. Trying to extract more than one has unexpected results.

```
lvec[[c(4,2)]] # the [[2]] element of lvec[[4]] !!
```

```
## [1] "thin"
```

```
# Error when you do this: lvec$c("hair", "weight")
```

Subsetting factors

- ▶ Subsetting may remove all instances of a level, but the level will be retained in the data structure

```
trt[1:3]
```

```
## [1] drug1    placebo placebo  
## Levels: placebo drug1 drug2
```

- ▶ If subsetting is intended to remove a level of the factor, use `drop=TRUE`

```
trt[1:3,drop=TRUE]
```

```
## [1] drug1    placebo placebo  
## Levels: placebo drug1
```

Subsetting and assignment

- ▶ You can combine subsetting and assignment to change the value of vectors.

```
avec
```

```
##      age weight height  
##      54    210     77
```

```
avec[2] <- 220  
avec
```

```
##      age weight height  
##      54    220     77
```

Assignment to vector elements

- ▶ To assign to a vector element, it is clearer to use `[[` rather than `[`.
- ▶ Also, for lists, assignment with `[` requires that the replacement element be of length 1; `[[` does not have this restriction

```
lvec[3:4] <- c("Hi", "there")  
lvec[3:4]
```

```
## $height  
## [1] "Hi"  
##  
## $hair  
## [1] "there"
```

```
lvec[4] <- c("All", "of", "this")
```

```
## Warning in lvec[4] <- c("All", "of", "this"): number of items to replace is  
## a multiple of replacement length
```

```
lvec[4] # Only used first element of replacement vector
```

```
## $hair  
## [1] "All"
```

```
lvec[[4]] <- c("All", "of", "this")  
lvec[3:4]
```

```
## $height  
## [1] "Hi"  
##  
## $hair  
## [1] "All" "of" "this"
```

Matrices, data frames and tibbles

Matrices and data frames

- ▶ Matrices are implemented as atomic vectors with a “dim” attribute of length 2 (number of rows, number of columns).
- ▶ As an atomic vector, elements of a matrix must all be of the same type.
- ▶ Data frames are lists where each list element has the same length. Thus data frames can include columns of varying type.

Matrices

- ▶ Matrices can be created with the `matrix()` function as in

```
A <- matrix(1:4,nrow=2,ncol=2)
```

```
A
```

```
##      [,1] [,2]
```

```
## [1,]    1    3
```

```
## [2,]    2    4
```

- ▶ Here `1:4` is the same as `c(1,2,3,4)`

- ▶ The default is to read the data vector into the matrix column-by-column. To read row-by-row instead use the `byrow=TRUE` argument:

```
A <- matrix(1:4,nrow=2,ncol=2,byrow=TRUE)
```

```
A
```

```
##      [,1] [,2]  
## [1,]    1    2  
## [2,]    3    4
```

```
A <- matrix(c( 1, 2,  
              3, 4),ncol=2,nrow=2,byrow=TRUE)
```

Combining matrices

- Combine matrices with `rbind()` and `cbind()`:

```
rbind(A,matrix(c(5,6),nrow=1,ncol=2))
```

```
##      [,1] [,2]  
## [1,]    1    2  
## [2,]    3    4  
## [3,]    5    6
```

```
cbind(A,A)
```

```
##      [,1] [,2] [,3] [,4]  
## [1,]    1    2    1    2  
## [2,]    3    4    3    4
```

Matrix attributes

- ▶ Matrices have a type, dimension and optional attributes such as dimnames (row and column names).

```
typeof(A)
```

```
## [1] "double"
```

```
dim(A)
```

```
## [1] 2 2
```

```
colnames(A) <- c("var1","var2")
rownames(A) <- c("subj1","subj2")
A
```

```
##      var1 var2
## subj1    1    2
## subj2    3    4
```

```
str(A)
```

```
##  num [1:2, 1:2] 1 3 2 4
## - attr(*, "dimnames")=List of 2
##  ..$ : chr [1:2] "subj1" "subj2"
##  ..$ : chr [1:2] "var1" "var2"
```

Subsetting matrices

- ▶ Subset with `[]` and a comma to separate rows from columns:

```
A[1,1]
```

```
## [1] 1
```

```
A[1,]
```

```
## var1 var2
```

```
##    1    2
```

```
A[,1]
```

```
## subj1 subj2
```

```
##    1    3
```

- ▶ When a subsetting operation leads to a vector, the dimension of the object is “dropped” from 2 to 1. To prevent this use `drop=FALSE`:

```
A[1,,drop=FALSE]
```

```
##      var1 var2
```

```
## subj1    1    2
```

Extracting elements from matrices

- ▶ Can use `[[` to extract elements, but this is not necessary because of the way subsetting to a single element drops to a vector of length 1 by default:

```
A[[1,1]]
```

```
## [1] 1
```

```
A[1,1]
```

```
## [1] 1
```

Coercion: Matrices to/from vectors

- ▶ We have already seen how `matrix()` coerces a vector to a matrix
- ▶ `as.vector()` applied to a matrix removes the `dim` attribute and creates a vector by concatenating columns:

```
A
```

```
##      var1 var2
## subj1    1    2
## subj2    3    4
```

```
as.vector(A)
```

```
## [1] 1 3 2 4
```

Data frames

- ▶ Data frames (class `data.frame`) are the usual way to store data in R.
 - ▶ Rows are intended to be observational units, columns variables
 - ▶ Implemented as a list (columns are list elements), but also behave like a matrix in terms of combining and subsetting.
- ▶ Create with `data.frame`:

```
set.seed(1)
n <- 4
x <- 1:n; y <- rnorm(n,mean=x,sd=1) # multiple commands separated by ;
dd <- data.frame(x=x,y=y) # like making a list
str(dd)
```

```
## 'data.frame':    4 obs. of  2 variables:
## $ x: int  1 2 3 4
## $ y: num  0.374 2.184 2.164 5.595
```

```
dd
```

```
##      x      y
## 1 1 0.3735462
## 2 2 2.1836433
## 3 3 2.1643714
## 4 4 5.5952808
```

Row and column names

- ▶ Get and set with `rownames()` and `colnames()`, respectively.
- ▶ `names()` also gets and sets the column names
- ▶ `rownames()` and `row.names()` both can the row names of a matrix or a dataframe, but for a data frame, value for `rownames` should be a character vector of non-duplicated and non-missing names (this is enforced).

```
colnames(dd); names(dd)
```

```
## [1] "x" "y"
```

```
## [1] "x" "y"
```

```
rownames(dd) <- paste0("subj", 1:nrow(dd))  
rownames(dd)
```

```
## [1] "subj1" "subj2" "subj3" "subj4"
```

Subsetting data frames like a list

```
dd$x
```

```
## [1] 1 2 3 4
```

```
dd[[1]]
```

```
## [1] 1 2 3 4
```

```
dd[1] # also try dd[1,]
```

```
##      x
```

```
## subj1 1
```

```
## subj2 2
```

```
## subj3 3
```

```
## subj4 4
```

```
c( typeof(dd$x),typeof(dd[[1]]),typeof(dd[1]) )
```

```
## [1] "integer" "integer" "list"
```

```
c( class(dd$x), class(dd[[1]]), class(dd[1]) )
```

```
## [1] "integer"      "integer"      "data.frame"
```

Subsetting and combining data frames like a matrix

```
dd[1:2,]
```

```
##           x           y
## subj1 1 0.3735462
## subj2 2 2.1836433
```

```
zz = data.frame(z=runif(4))
cbind(dd,zz)
```

```
##           x           y           z
## subj1 1 0.3735462 0.62911404
## subj2 2 2.1836433 0.06178627
## subj3 3 2.1643714 0.20597457
## subj4 4 5.5952808 0.17655675
```

tibbles

- ▶ A tidyverse replacement (or extension) of the data frame with different default behaviour.
- ▶ See section 3.6 for a discussion of some of the differences.

```
library(tibble)
tt <- tibble(x = 1:3, y = letters[1:3])
typeof(tt)
```

```
## [1] "list"
```

```
attributes(tt)
```

```
## $class
## [1] "tbl_df"      "tbl"        "data.frame"
##
## $row.names
## [1] 1 2 3
##
## $names
## [1] "x" "y"
```

More on subsetting

- ▶ one-dimensional subsets of data frames are coerced to atomic vectors, but not so with tibbles.

```
dd[,1]; dd[1,1]
```

```
## [1] 1 2 3 4
```

```
## [1] 1
```

```
tt[,1]; tt[1,1]
```

```
## # A tibble: 3 x 1
```

```
##       x
```

```
##   <int>
```

```
## 1     1
```

```
## 2     2
```

```
## 3     3
```

```
## # A tibble: 1 x 1
```

```
##       x
```

```
##   <int>
```

```
## 1     1
```

List columns

- ▶ One way that tibbles improve on data frames is easier handling of columns whose elements are lists.

```
tibble(  
  x = 1:3,  
  y = list(1:2, 1:3, 1:4) # lists of different length on each subject  
)
```

```
## # A tibble: 3 x 2  
##       x y  
##   <int> <list>  
## 1     1 1 <int [2]>  
## 2     2 2 <int [3]>  
## 3     3 3 <int [4]>
```

Logical and relational operators

Logical operators

- ▶ The basic logical operators are described in `help("Logic")`.
- ▶ `!` is NOT
- ▶ `&` and `&&` are AND, with `&` acting vector-wise and `&&` acting on scalars
- ▶ `|` and `||` are OR, with `|` acting vector-wise and `||` acting on scalars
- ▶ Make sure you understand the following:

```
x <- c(TRUE,TRUE,FALSE); y <- c(FALSE,TRUE,TRUE)
!x ; x&y ; x&&y ; x|y ; x||y
```

```
## [1] FALSE FALSE TRUE
```

```
## [1] FALSE TRUE FALSE
```

```
## Warning in x && y: 'length(x) = 3 > 1' in coercion to 'logical(1)'
```

```
## Warning in x && y: 'length(x) = 3 > 1' in coercion to 'logical(1)'
```

```
## [1] FALSE
```

```
## [1] TRUE TRUE TRUE
```

```
## Warning in x || y: 'length(x) = 3 > 1' in coercion to 'logical(1)'
```

```
## [1] TRUE
```

- ▶ Notice how `&&` and `||` act on the first element of the vectors `x` and `y` and ignore all the rest.

Relational operators

- ▶ Relational operators can be used to compare values in atomic vectors
 - ▶ See `help("Comparison")`
- ▶ `>` is greater than, `>=` is greater than or equal
- ▶ `<` is less than, `<=` is less than or equal
- ▶ `==` is equal and `!=` is not equal
- ▶ Make sure you understand the following:

```
x <- 1:3; y <- 3:1  
x>y ; x>=y ; x<y ; x<=y ; x==y ; x!=y
```

```
## [1] FALSE FALSE  TRUE
```

```
## [1] FALSE  TRUE  TRUE
```

```
## [1]  TRUE FALSE FALSE
```

```
## [1]  TRUE  TRUE FALSE
```

```
## [1] FALSE  TRUE FALSE
```

```
## [1]  TRUE FALSE  TRUE
```

Subsetting vectors with logical expressions

- Can subset with logicals and [:

```
avec
```

```
##    age weight height  
##    54    220     77
```

```
avec>100
```

```
##    age weight height  
## FALSE    TRUE  FALSE
```

```
avec[avec>100]
```

```
## weight  
##    220
```

```
avec[avec>54 & avec<100]
```

```
## height  
##     77
```

Subsetting matrices with logical expressions

- ▶ Can also subset matrices, but results may not be as expected:

```
A
```

```
##           var1 var2
## subj1      1    2
## subj2      3    4
```

```
A>1
```

```
##           var1 var2
## subj1 FALSE TRUE
## subj2  TRUE TRUE
```

```
A[A>1] # coerces to a vector
```

```
## [1] 3 2 4
```

Subset and assign with logical expressions

- ▶ Combine subset and assign to change the value of objects

```
A[A>1] <- 9
```

```
A
```

```
##      var1 var2
```

```
## subj1   1   9
```

```
## subj2   9   9
```

- ▶ In the above substitution, the vector 9 is shorter than the three elements in A>1 so R “recycles” the 9 three times.

Be careful about recycling:

```
A[A>1] <- c(-10,10) # Throws a warning
```

```
## Warning in A[A > 1] <- c(-10, 10): number of items to replace is not  
## of replacement length
```

```
A # R used c(-10,10), then just the -10
```

```
##      var1 var2  
## subj1    1  10  
## subj2  -10 -10
```
